FOREWORD

The Pond Dynamics/Aquaculture Collaborative Research Support Program (PD/A CRSP) represents an international community of researchers and institutions dedicated to strengthening health and nutrition in developing countries by improving the efficiency of pond aquaculture systems. It is one of several agricultural CRSPs supported by the U.S. Agency for International Development under the authority of Title XII of the International Development and Food Assistance Act of 1975.

The "Global Experiment" in Pond Dynamics/Aquaculture is the major CRSP research activity, covering the period from 1982 to 1987. The Global Experiment was designed to quantitatively describe the physical, chemical and biological principles of pond culture systems. The information gained from the Global Experiment will be used to improve production technologies and develop quantitative production functions to facilitate rigorous economic analyses of aquaculture systems.

Standardization is a key element of the Global Experiment. Standardization permits the comparison of data from diverse geographic locations. The experimental design involves monitoring specified environmental and fish production variables in accordance with standardized work plans in twelve or more ponds at each of seven geographical locations. The variables observed, frequency of observation, and materials and methods are uniform for all locations. The field data are filed in a centralized data base, called the CRSP Central Data Base. Statistical methods will be used to test hypotheses about correlations between variables and to evaluate the sources of variance within ponds, between ponds within locations, and between locations.

The CRSP Central Data Base will be used to develop predictive models of the processes occurring in pond culture systems. The models will be used to: provide guidance for ongoing and future research; predict the performance of existing and proposed pond systems subject to specific inputs and constraints; and improve the operation and efficiency of pond culture systems.

The Global Experiment includes three cycles of experiments. Each cycle consists of two series of observations, one during the dry season and one during the wet season. The objective of the first cycle is to create a detailed baseline of chemical, physical, and biological data on all ponds treated with a standard level of inorganic fertilizer. In the second experimental cycle, ponds treated with inorganic fertilizer are compared to ponds treated with organic fertilizer. In the third cycle, the responses of ponds to different levels of organic fertilizer are compared.

The goal of the Pond Dynamics/Aquaculture Collaborative Research Data Reports (referred to as Data Reports) is to record the CRSP Central Data Base and to present interpretations of site specific results. The Pond Dynamics/Aquaculture CRSP has conducted the Global Experiment at seven project sites in six developing countries: Thailand, Indonesia, the Philippines, Panama, Honduras, and Rwanda. The first volume of these reports provides descriptive information for each CRSP site. It presents the physical characteristics of each site, including a geographical sketch, climatology, and water and soil analyses. Experimental cycles are described in CRSP Work Plans One to Three, which are summarized in the first volume.

Volume One will serve as the reference volume for the entire report series. Subsequent volumes will focus on each site separately. Each Data Report will include one cycle (wet and dry seasons) of the Pond Dynamics/Aquaculture CRSP Global Experiment. Therefore, with few exceptions, each project site will have three Data Reports devoted to it, representing the results of the three cycles of the Global Experiment. Cycle I of the Global Experiment in Honduras is presented in this volume.

INTRODUCTION

The results of the Cycle I Pond Dynamics/Aquaculture (PD/A) CRSP dry and rainy season experiments, conducted at the El Carao Aquacultural Experiment Station, Comayagua, Honduras, are reported herein. The station, located about 8 km from the city of Comayagua, is the largest of a series of aquacultural experiment stations operated by the General Directorate of Natural Renewable Resources (Dirección General de Recursos Naturales Renovables), Ministry of Natural Resources (Secretaría de Recursos Naturales). Facilities at the station have been described by Egna et al. (1987). The El Carao Station is used for CRSP research and for the production of tilapia and chinese carp fingerlings which are distributed to fish farmers. Other activities undertaken by the station's technical staff are extension and training.

The objective of this research was to quantify the physical, chemical, and biological characteristics of experimental ponds, stocked with *Oreochromis niloticus* and fertilized only with phosphorus, during the dry and rainy seasons (CRSP First Work Plan, undated). Fish yields after 150 days were evaluated, and dry and rainy season results were compared.

MATERIALS AND METHODS

Ten and twelve 0.1-ha earthen ponds located on the El Carao Aquacultural Experiment Station were used during the dry and rainy seasons, respectively. Triple superphosphate (TSP) fertilizer (46% P_2O_5) was applied biweekly to each pond at a rate of 8.7 kg TSP/ha. The fertilizer was dissolved in a bucket containing pond water. After several minutes of mixing the supernatant was dispersed over the pond surface, and the remaining undissolved fertilizer was washed into a woven plastic sack suspended at 25 cm depth. Any fertilizer remaining in the sack was dissolved prior to the next fertilizer application.

Ponds were stocked with male *Oreochromis niloticus* at a rate of 10,000/ha. At stocking, fingerlings averaged 13.1 g and 10.4 g during the dry and rainy seasons, respectively. Ponds for the dry season experiment were stocked on 12 January 1984 and all ponds were harvested on 13 June 1984, 150 days after stocking. Ponds for the rainy season experiment were stocked on 11 July 1984 and harvested on 10 December 1984, 150 days later. Ponds were managed according to guidelines given in the CRSP First Work Plan (undated).

Pond mud samples were collected using the methodology given in the CRSP First Work Plan (undated). Initial dry season samples were analyzed in the United States. The final dry season samples, which also served as the initial rainy season samples, and the final rainy season samples were analyzed at a soils laboratory in Honduras.

Initial and final water samples were collected from each pond, preserved according to the CRSP First Work Plan (undated), and analyzed for major/minor elements in the U.S. and in Honduras during the dry and rainy seasons, respectively.

Water quality samples were collected monthly and analyzed according to the CRSP First Work Plan (undated). Certain exceptions to the stated methods are detailed below:

1) Solar Radiation

A Belfort pyrhelimeter was used to measure total solar radiation ($\text{g-cal/cm}^2\text{-day}$). On 20 September 1984, a LI-COR LI-1776 solar monitor (E/m^2) was installed. Both readings were recorded.

2) Wind Speed and Direction

Wind speed and direction data were obtained from the Honduran Air Force Base at Palmerola, located approximately 8 km S-SE of the station. Hourly spot readings were averaged to determine daily means. Beginning 30 November 1984, a Weathertronics recording anemometer was installed on the station. In both cases instrument height was 2.44 m.

3) Air Temperatures

Equipment was installed on 16 January 1984.

4) Pond Water Temperatures

Equipment was installed on 29 January 1984 and 22 July 1984.

5) Diurnal Dissolved Oxygen Studies

The first three dry season diurnal studies ran from 1500 to 1500 hours, while the remaining studies were conducted from 0600 to 0600 hours. All rainy season studies ran from 0600 a.m. to 0600 hours.

6) pH

Weekly dry season pH measurements began on 23 April 1984.

7) Chlorophyll *a*

Not done for lack of proper equipment.

8) Primary Productivity

Dry and rainy season primary productivity was determined monthly using the free-water diurnal curve method (Hall and Moll, 1975). Dissolved oxygen was measured as part of the diurnal sampling, using a polarographic dissolved oxygen meter, at 4-hour intervals and at depths of 0.25, 0.50, and 0.75 m. Measured values were corrected for oxygen diffusion across the air-water interface using an empirical relationship relating the oxygen transfer coefficient to wind speed (Banks and Herrera, 1977).

9) Phytoplankton

Relative abundance by major groups during dry season; done approximately every three days beginning 1 March 1984.

10) Zooplankton

Quantitative analysis to major groups on a weekly basis beginning 19 July 1984.

Data were analyzed using t-test and regression analysis using the StatView SE + Graphics statistical data analysis package (Feldman et al., 1988). Ponds B-4 and B-5 were excluded from the comparisons because the data obtained from these ponds during the rainy season were so different from the remaining ponds. Data were reported as means by pond, and means \pm standard error. Differences were declared significant at an alpha level of 0.05.

RESULTS

FISH YIELD

The mean yield of tilapia during the dry season (547 ± 36 kg/ha) was significantly greater than during the rainy season (334 ± 25 kg/ha) (Tables 1 and 2, Figure 1). Although the mean initial individual fish weights were different for each season, an analysis of covariance indicated no significant effect of stocking weight on subsequent growth. No seasonal difference in fish survival was observed. Tilapia reproduction in the experimental ponds was significantly greater during the rainy season. Human error during the sexing of the fish was the cause of differences in the extent of reproduction.

WATER QUALITY VARIABLES

Results of water quality analyses are summarized by pond in Table 3, and by season in Figures 2 to 13. Seasonal water quality means are compared in Table 4.

BIOLOGICAL VARIABLES

Primary Productivity and Community Respiration

Net primary productivity during the dry season (1.62 ± 0.13 g O₂/m³ - day) was significantly greater than during the rainy season (0.75 ± 0.11 g O₂/m³ - day). Dry season gross primary productivity (3.41 ± 0.23 g O₂/m³ - day) was significantly greater than rainy season gross primary productivity (2.59 ± 0.17 g O₂/m³ - day). Community respiration during the dry season (3.56 ± 0.23 g O₂/m³ - day) was similar to that of the rainy season (3.68 ± 0.22 g O₂/m³ - day). Clay turbidity was present in ponds during both seasons, and limited the amount of light

available for photosynthesis. Greater clay turbidity, caused by runoff during the rainy season, was probably responsible for reduced primary productivity.

Phytoplankton

Green algae dominated phytoplankton populations on the majority of the sampling dates during the dry season. Whereas blue-green algae ranged in abundance from rare to abundant, they were, on the average, common. Diatoms were rare to common. The most common genera were: *Scenedesmus* (green algae), *Ankistrodesmus* and *Anabaena* (blue-green algae), *Navicula* and *Fragilaria* (diatoms).

Zooplankton

Generally, cyclopoid copepods dominated zooplankton populations during the dry season, while cladocerans and rotifers were present in intermediate numbers. The total number of zooplankters decreased over the course of the experiment (Figure 14).

Throughout the rainy season experiment rotifers were the dominant zooplankton, and generally represented 50% or more of the total zooplankton population (Figure 15). Nauplii and cyclopoid copepods were the second and third most abundant. The total number of zooplankton decreased in all groups over the course of the experiment.

Secchi Disk Visibility

Mean Secchi disk visibility (SDV) was greater during the dry season (16.1 ± 0.9 cm) than during the rainy season (13.5 ± 0.6 cm). SDV behaved in a similar manner during both seasons: initial SDVs decreased to a range of 11 - 16 cm within the first month, and remained at this level throughout the remainder of the experiment (Table 5). Clay turbidity was the primary form of turbidity during both seasons.

WATER USAGE

Ponds gained a mean of 1095 m³ and 1007 m³ water/pond from all sources during the dry and rainy seasons, respectively (Table 6). Rain water represented 18% of gains during the dry season compared with 56% in the rainy season. Reservoir water was the source for remaining gains. Water losses were comparable during both seasons. It was not possible to separate losses into components of seepage, evaporation, or overflow.

SOIL ANALYSES

Results of the pond mud analyses are presented by pond in Tables 7 to 9, and seasonal comparisons are made in Table 10. It should be noted that the final soil sample from one season was used as the initial sample for the following season as the turn-around-time was less than one month.

MINOR ELEMENTS IN WATER

Different laboratories were used to analyze each season's initial (Tables 11 and 13) and final (Table 12 and 14) samples; it is not known how this affects between-season comparisons. Relationships between mean initial and mean final concentrations are shown in Table 15.

STATION ENVIRONMENT

Solar Radiation

The mean daily (total) solar radiation for the dry season (439.2 g-cal/cm^2) was similar to the mean for the rainy season (408.1 g-cal/cm^2) (Table 16). Similar ranges of daily total solar radiation were observed during both seasons.

Rainfall

Rainy season precipitation (56.5 cm) was over 100% greater than dry season precipitation (20.0 cm). It rained 61 days during the rainy season and 34 days during the dry season. The number of rainy days and total rainfall per month were: January (13 - 30), 4 days, 0.73 cm; February, 4 days, 1.16 cm; March, 3 days, 0.15 cm; April, 3 days, 0.26 cm; May, 12 days, 12.15 cm; June (1 - 13), 8 days, 5.58 cm; July (11 - 30), 11 days, 6.98 cm; August, 17 days, 9.34 cm; September, 16 days, 28.85 cm; October, 12 days, 11.01 cm; November, 3 days, 0.29 cm; and, December (1 - 11), 2 days, 0.02 cm. Rains generally fell during the late afternoon and evening hours during both seasons.

Wind

Mean daily wind speed, by month, was: January 11 to 31, 12.8 kph; February, 12.5 kph; March, 10.2 kph; April, 9.0 kph; May, 8.5 kph; June 1 to 13, 7.5 kph; July 11 to 30, 8.8 kph; August, 8.3 kph; September, 7.7 kph;

October, 10.2 kph; November, 12.0 kph; and, December 1-11, 6.3 kph. Wind direction was predominantly from the N-NW. There were no seasonal differences in wind speed or direction.

Air Temperature

Although air temperatures tended to increase slightly during the dry season, the opposite was true during the rainy season (Figures 16 and 17). The mean daily maximum was more variable during the dry season, whereas the mean daily minimum was more variable during the rainy season.

RELATIONSHIPS BETWEEN BIOLOGICAL VARIABLES

Dry season tilapia yield was significantly correlated with net primary productivity ($r^2 = 0.68$). Net daily tilapia yield was significantly correlated with net primary productivity ($r^2 = 0.695$). Combined tilapia yield (both seasons) was significantly correlated to net primary productivity ($r^2 = 0.795$) (Figure 18).

DISCUSSION

Mean net and gross primary productivity and tilapia yield were greater during the dry season. Coefficients of variation (CV) for fish yield were 23.9% and 20.8% for the rainy and dry seasons, respectively. Net total yield CV's were 35.9% and 26.3% during the rainy and dry seasons, respectively. The greater rainy season CV was attributed to the greater extent to which tilapia reproduction occurred.

Twelve ponds were used during the rainy season cycle as opposed to 10 ponds during the dry season experiment. The two ponds previously excluded (B-4 and B-5) had a recent history of organic fertilization. An obvious residual effect of this fertilization on the fertility of these two ponds was observed during the present experiment, especially in terms of fish yield and primary productivity. The coefficient of variation for total net yield was 71% when all 12 ponds were included, but dropped to 36% when B-4 and B-5 were excluded. Coefficients of variation for net and gross primary productivity and community respiration decreased from 67%, 46%, and 40%, respectively, to 45%, 21%, and 19%, respectively, when ponds B-4 and B-5 were excluded. Water quality variables were much less affected by the previous fertilization history of the ponds. Coefficients of variation ranged from 11 - 22% for water quality parameters when all 12 ponds were considered. When ponds B-4 and B-5 were excluded, the coefficients of variation either decreased or remained unchanged, and CV's varied from 10 - 17%.

It had been expected that fish yields would average 1000 kg/ha during each season. Although reports in the literature suggested that this was a reasonable expectation, the present results indicate otherwise. The turbidity in ponds, which was caused by suspended clay particles, reduced light penetration, and was probably the principal factor limiting production, as there appeared to be sufficient quantities of carbon, nitrogen and phosphorus in the pond water. Although incoming water generally had a slightly milky color, water appeared to be more turbid during the rainy season as a result of surface runoff. However, much of the turbidity was probably caused by the suspension of fine clay particles from the bottom muds by wind-induced water circulation. The low organic matter content of the bottom muds most likely made it easier for this fine clay to be brought into suspension.

Water quality means were generally greater during the dry season, in part because of the concentration of constituents resulting from evaporation, and in part because of dilution and losses of constituents from ponds caused by rainfall during the rainy season.

Table 15. Relationships between mean initial and mean final concentrations of chemical variables in pond waters during the Cycle I dry and rainy season experiments.

Variable	Dry Season	Rainy Season	Initial Values	Final Values
Calcium	initial = final	initial < final	---	---
Magnesium	initial < final	initial < final	dry = rainy	dry > rainy
Sodium	initial < final	initial < final	dry < rainy	dry = rainy
Potassium	initial = final	initial < final	dry < rainy	dry = rainy
Iron	initial < final	initial = final	---	dry > rainy
Manganese	initial < final	initial = final	---	dry > rainy
Boron	initial = final	initial = final	---	initial = final

Table 16. Mean monthly total solar radiation (g-cal/cm² per day) and photosynthetically active solar radiation (E/m² per day) during the Cycle I dry and rainy season experiments.

Time Period	Total Solar Radiation	Time Period	Photosynthetically Active Solar Radiation
13 - 31 January 1984	402.1	---	---
1 - 29 February 1984	427.6	---	---
1 - 31 March 1984	476.1	---	---
1 - 30 April 1984	489.9	---	---
1 - 31 May 1984	443.0	---	---
1 - 15 June 1984	451.9	---	---
11 - 31 July 1984	437.2	---	---
1 - 31 August 1984	424.9	---	---
1 - 30 September 1984	406.4	21 - 30 September 1984	42.83
1 - 31 October 1984	434.5	1 - 31 October 1984	47.02
1 - 30 November 1984	379.5	1 - 30 November 1984	37.47
1 - 10 December 1984	366.1	1 - 11 December 1984	34.30

Figure 1. Growth of male *Oreochromis niloticus* (10,000/ha) in ponds during the Cycle I dry and rainy season experiments.

Figure 2. Mean total alkalinity, total hardness, and calcium hardness in ponds during the Cycle I dry season experiment.

Figure 3. Mean total alkalinity, total hardness, and calcium hardness in ponds during the Cycle I rainy season experiment.

Figure 4. Mean ammonia-nitrogen and nitrate-nitrogen in ponds during the Cycle I dry season experiment.

Figure 5. Mean ammonia-nitrogen and nitrate-nitrogen in ponds during the Cycle I rainy season experiment.

Figure 6. Mean total phosphorus and soluble orthophosphate in ponds during the Cycle I dry season experiment.

Figure 7. Mean total phosphorus and soluble orthophosphate in ponds during the Cycle I rainy season experiment.

Figure 8. Example of change in mean soluble orthophosphate concentration in ponds over 14 days after fertilization with triple superphosphate (day 0), during the Cycle I dry and rainy season experiments..

Figure 9. Mean weekly maximum - minimum water temperature at 0.25-m depth in ponds during the Cycle I dry season experiment.

Figure 10. Mean weekly maximum - minimum water temperature at 1.25-m depth in ponds during the Cycle I dry season experiment.

Figure 11. Mean weekly maximum - minimum water temperature at 0.25-m depth in ponds during the Cycle I rainy season experiment.

Figure 12. Mean weekly maximum - minimum water temperature at 1.25-m depth in ponds during the Cycle I rainy season experiment.

Figure 13. Mean diurnal change in dissolved oxygen in ponds during the Cycle I dry and rainy season experiments. Time of day in 24-hour time system.

Figure 14. Zooplankton dynamics in ponds during the Cycle I dry season experiment.

Figure 15. Zooplankton dynamics in ponds during the Cycle I rainy season experiment.

Figure 16. Mean daily maximum - minimum air temperatures during the Cycle I dry season experiment.

Figure 17. Mean daily maximum - minimum air temperatures during the Cycle I rainy season experiment.

Figure 18. Relationship between mean tilapia yield and net primary productivity in ponds during the Cycle I dry and rainy season experiments.

APPENDIX.

Complete Set of Data from Cycle I of the Pond/Dynamics Aquaculture CRSP in Honduras.
